GitHub Workflow & Development-Agent Rules

Permanent repository workflow after V1.

1. Branches

```
main = stable/releasable
feature/* = bounded feature work
fix/* = bug fixes
research/* = experiments
release/* = release preparation
```

Do not develop directly on main for material changes. Keep research isolated.

2. Workflow

```
Task
↓
Antigravity plan
↓
Implementation agent
↓
Tests
↓
Git diff review
↓
Antigravity review
↓
PR
↓
CI
↓
User approval
↓
Merge
```

Each PR explains what changed, why, tests, risks, migrations, configuration changes and rollback considerations.

3. Commit & Security

Use focused commits. Never mix unrelated refactors and trading logic. Never commit secrets, broker credentials, model tokens or local environment files.

4. CI

Run formatting/linting, unit tests, integration tests and frontend checks. Trading-critical changes require deterministic tests for risk, order state, P/L and failure handling.

5. Release

```
CHANGELOG
↓
Version bump
↓
Full tests
↓
Security/secret scan
↓
Docs verification
↓
Release commit
↓
Git tag
↓
GitHub release
↓
Deployment verification
```

6. Agent Rule

Antigravity creates tasks and reviews changes. The implementation agent modifies only necessary files. User approves architecture changes and live-trading changes.
